

How to add a Widget to the front page.

Widgets are small tools or graphs. Most of the Widgets currently in use are based on **disposition** data.

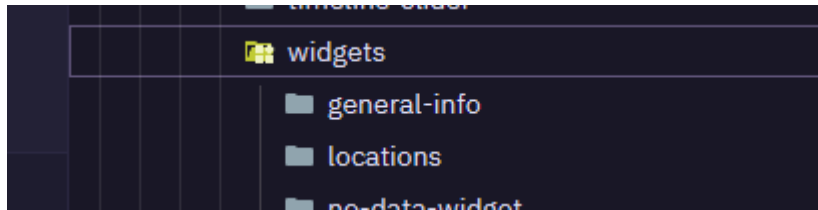

1. Get the project running. Check what kind of data your widget needs, in case it's more than **provisions** and locations, there **might not be** an endpoint for the required data.
2. Update YouTrack so others know you are working on that task. You don't want to work on a task just for someone else to complete it before you. The Board **is being used** for coordinating on what to work on.

3. You **should get yourself a reference**; How did others make their widgets and what is important for using them?
4. Check if there are libraries for your widget. You **shouldn't redo** the work of others.

5. Make a git branch using the following pattern: feature/widget-YOUR-WIDGET. Git **is used for** managing project versions such as the one you will be working on.
6. Make a new folder inside frontend/src/app/components/widgets. This folder should contain all widgets.

7. Think of a fitting name you **can use** for all cases that don't conflict with other names or the programming language. Names **must differ** from shared components. The name **is used** to place the widget, and the engine **can't tell** what is used when the names don't differ.
8. You **should use this name** for all things related to your widget. Rename the folder you made to that name. Make the necessary TypeScript and HTML files.
9. You should use the existing components inside the project, so go and take a look at the shared components.
10. Now you **can start** implementing the widget. Start writing the code needed for your widget.
11. If the widget looks **serviceable**, add a short documentation on how to use it. Add a link to external resources if those **are used** in the widget and nowhere else inside the project. If you don't want to **refactor code**, you must make it right the first time.
12. Do some tests yourself, check how it looks on different browsers or with dark mode enabled.
13. Create a merge request for your branch. For your changes to be added to the main project, your branch **must now be merged**.
14. Notify your team that you **would like your merge request looked at** by someone. **In case you are sure** you can **revert mistakes** and understand how your code and the code of the main branch differ, you **needn't ask for permission** and **can push** the changes without review.
15. In case the main branch has been altered between your work, you **might have to pull** those changes into your branch.
16. Update YouTrack and notify your team once the merge **has been completed**.
